

# Summary

---

- ▶ Graph visits
- ▶ Visits in JGraphT

# Visit Algorithms

---

- ▶ **Visit =**
  - ▶ Systematic exploration of a graph
  - ▶ Starting from a ‘source’ vertex
  - ▶ Reaching all reachable vertices
- ▶ **Main strategies**
  - ▶ Breadth-first visit (“in ampiezza”)
  - ▶ Depth-first visit (“in profondità”)

# Breadth-First Visit

---

- ▶ Also called Breadth-first search (BFV or BFS)
- ▶ All reachable vertices are visited “by levels”
  - ▶  $L$  – level of the visit
  - ▶  $S_L$  – set of vertices in level  $L$
  - ▶  $L=0, S_0 = \{ v_{\text{source}} \}$
  - ▶ Repeat while  $S_L$  is not empty:
    - ▶  $S_{L+1}$  = set of all vertices:
      - not visited yet, and
      - adjacent to at least one vertex in  $S_L$
    - ▶  $L=L+1$

# Example

Source = s  
L = 0  
 $S_0 = \{s\}$

# Example

$L = I$   
 $S_0 = \{s\}$   
 $S_1 = \{r, w\}$

# Example

$L = 2$   
 $S_1 = \{r, w\}$   
 $S_2 = \{v, t, x\}$

# Example

$L = 3$   
 $S_2 = \{v, t, x\}$   
 $S_3 = \{u, y\}$

# BFS Tree

---

- ▶ The result of a BFV identifies a “visit tree” in the graph:
  - ▶ The tree root is the source vertex
  - ▶ Tree nodes are all graph vertices
    - ▶ (in the same connected component of the source)
  - ▶ Tree are a subset of graph edges
    - ▶ Those edges that have been used to “discover” new vertices.

# BFS Tree

---

# Minimum (shortest) paths

---

- ▶ Shortest path: the minimum number of edges on any path between two vertices
- ▶ The BFS procedure computes all minimum paths for all vertices, starting from the source vertex
- ▶ NB: unweighted graph : path length = number of edges

# Depth First Visit

---

- ▶ Also called Depth-first search (DFV or DFS)
- ▶ Opposite approach to BFS
- ▶ At every step, visit one (yet unvisited) vertex, adjacent to the last visited one
- ▶ If no such vertex exist, go back one step to the previously visited vertex
- ▶ Lends itself to recursive implementation
  - ▶ Similar to tree visit procedures

# DFS Algorithm

---

- ▶ DFS(Vertex  $v$ )
  - ▶ For all (  $w : \text{adjacent\_to}(v)$  )
    - ▶ If( not visited ( $w$ ) )
      - Visit ( $w$ )
      - DFS( $w$ )
  
- ▶ Start with: DFS(source)

# Example

---

Source = s

# Example

Source = s  
Visit r

# Example

Source = s  
Visit r  
Visit v

# Example

---

Source = s  
Back to r  
Back to s  
Visit w

# Example

Source = s  
Visit w  
Visit t

# Example

Source = s  
Visit w  
Visit t  
Visit u

# Example

---

Source = s  
Visit w  
Visit t  
Visit u  
Visit y

# Example

---

Source = s  
Visit w  
Visit t  
Visit u  
Visit y  
Visit x

# Example

Back to s = STOP

Source = s  
Back to y  
Back to u  
Back to t  
Back to w

DFS tree

# Example

Directed graph

# Example

DFS visit  
(sources: s, t)

# Complexity

---

- ▶ Visits have linear complexity in the graph size
  - ▶ BFS :  $O(V+E)$
  - ▶ DFS :  $\Theta(V+E)$
- ▶ N.B. for dense graphs,  $E = O(V^2)$

# JGraphT and visits

---

- ▶ Visits are called “traversals”
- ▶ Implemented through **Iterator** classes
- ▶ Package **org.jgrapht.traverse**

# Graph traversal classes

## Package org.jgrapht.traverse

Graph traversal means.

### Interface Summary

Interface	Description
<b>GraphIterator</b> <V,E>	A graph iterator.

### Class Summary

Class	Description
<b>AbstractGraphIterator</b> <V,E>	An empty implementation of a graph iterator to minimize the effort required to implement graph iterators.
<b>BreadthFirstIterator</b> <V,E>	A breadth-first iterator for a directed or undirected graph.
<b>BreadthFirstIterator.SearchNodeData</b> <E>	Data kept for discovered vertices.
<b>ClosestFirstIterator</b> <V,E>	A closest-first iterator for a directed or undirected graph.
<b>CrossComponentIterator</b> <V,E,D>	Provides a cross-connected-component traversal functionality for iterator subclasses.
<b>DegeneracyOrderingIterator</b> <V,E>	A degeneracy ordering iterator.
<b>DepthFirstIterator</b> <V,E>	A depth-first iterator for a directed or undirected graph.
<b>LexBreadthFirstIterator</b> <V,E>	A lexicographical breadth-first iterator for an undirected graph.
<b>MaximumCardinalityIterator</b> <V,E>	A maximum cardinality search iterator for an undirected graph.
<b>RandomWalkIterator</b> <V,E>	Deprecated. <i>Use <a href="#">RandomWalkVertexIterator</a> instead.</i>
<b>RandomWalkVertexIterator</b> <V,E>	A random walk iterator.
<b>TopologicalOrderIterator</b> <V,E>	A topological ordering iterator for a directed acyclic graph.

# Graph iterators

---

- ▶ May be initialized with a start vertex, a set of start vertices, or no vertices (the algorithm chooses)
- ▶ Usual `hasNext()` and `next()` methods
- ▶ Every time you call `next()` a new vertex `V` is returned
- ▶ When `hasNext()==false`, no more reachable vertices exist

# Types of traversal iterators

---

- ▶ **BreadthFirstIterator**
- ▶ **DepthFirstIterator**
- ▶ **ClosestFirstIterator**
  - ▶ The metric for *closest* here is the path length from a start vertex. `Graph.getEdgeWeight(Edge)` is summed to calculate path length. Optionally, path length may be bounded by a finite radius.
- ▶ **TopologicalOrderIterator**
  - ▶ A topological sort is a permutation  $p$  of the vertices of a graph such that an edge  $\{i,j\}$  implies that  $i$  appears before  $j$  in  $p$ . Only directed acyclic graphs can be topologically sorted.

# Processing during traversal

---

- ▶ May register event listeners to traversal steps
  - ▶ void **addTraversalListener**(TraversalListener<V,E> l)
- ▶ TraversalListeners may react to:
  - ▶ Edge traversed
  - ▶ Vertex traversed
  - ▶ Vertex finished
  - ▶ Connected component started
  - ▶ Connected component finished

# Spanning Tree

---

- ▶ `BreadthFirstIterator`<sup>(\*)</sup> contains the method
  - ▶ `public E getSpanningTreeEdge(V v)`
- ▶ that allows us to re-construct the spanning tree
  - ▶ In reverse order... from a vertex to its predecessor.
- ▶ It can be used to construct the shortest paths from the source of the visit to a reachable vertex

<sup>(\*)</sup> but not other iterator classes
